

CS 106B, Lecture 7

Sets and Maps

ADTs So Far

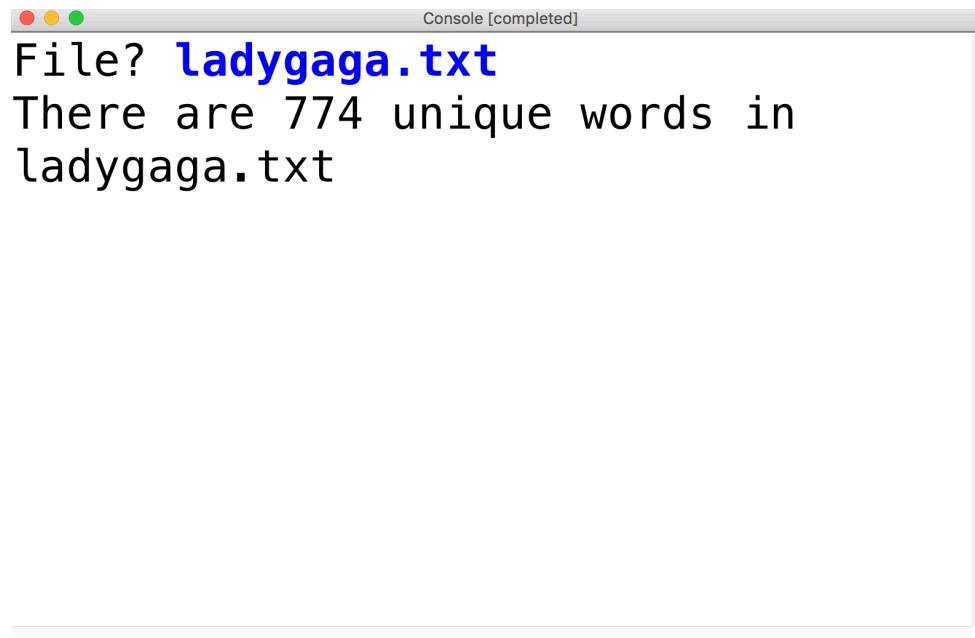

Today's Topics

- Sets (no duplicates allowed!)
 - Lexicons
- Maps (map a key to a value)

CountUniqueWords

- One basic statistic about a text is the number of unique words it has
 - Linguists and computer scientists frequently start analysis with the number of unique words
 - Good indication of vocabulary
- Problem: how can we determine the number of unique words in a file?

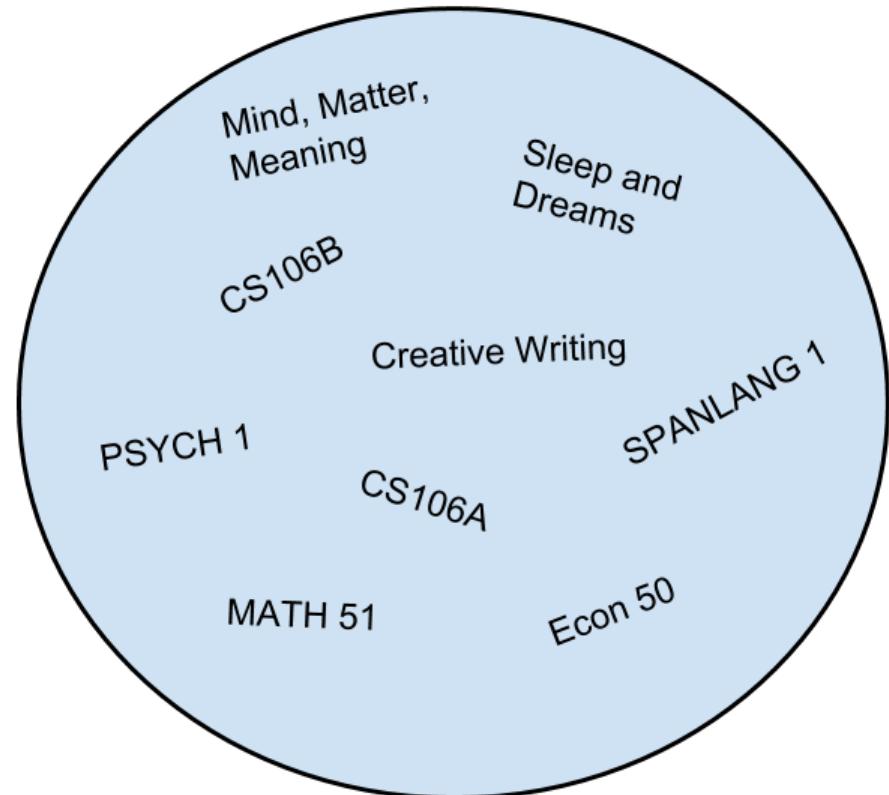

A screenshot of a Mac OS X terminal window titled "Console [completed]". The window shows the command "File? ladygaga.txt" in blue text, indicating the file being processed. Below it, the output "There are 774 unique words in ladygaga.txt" is displayed in black text.

Today's Topics

- Sets (no duplicates allowed!)
 - Lexicons
 - Maps (map a key to a value)

Sets

- Only answers question of membership
 - **No duplicates**
- Operations
 - `contains(elem)`
 - `add(elem)`
 - `remove(elem)`
- Comparison to Vector
 - Does not maintain insertion order
 - No duplicates
 - Really fast at finding membership

Stanford C++ sets (5.5)

- **Set**: implemented using a linked structure called a *binary tree*.
 - pretty fast; elements are stored in **sorted order**
 - values must have a < operation
- **HashSet**: implemented using a special array called a *hash table*.
 - *very* fast; elements are stored in **unpredictable order**
 - values must have a hashCode function (*provided for most standard types*)
 - variant: `LinkedHashSet` (*slightly slower, but remembers insertion order*)

How to choose: Do you need the elements to be in sorted order?

- If so: Use Set.
- If not: Use HashSet for the performance boost.

Looping over Sets

- Sets don't have indices, so we use a for-each loop
- Iterates in sorted order (alphabetical order for strings)
- Can't edit while we iterate

```
Set<string> friends;
friends.add("Leland");
friends.add("Kate");
```

```
// prints in alphabetical order
for (string myFriend : friends) {
    cout << "Hi, " << myFriend << endl;
    cout << "Let's get dinner." << endl;
}
```

Looping over a set

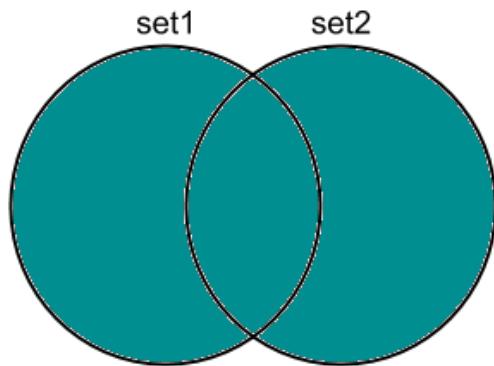

```
// forward iteration with for-each loop (read-only)
for (type name : collection) {
    statements;
}
```

- sets have no indexes; can't use normal for loop with index [i]
- Set iterates in sorted order; HashSet in unpredictable order

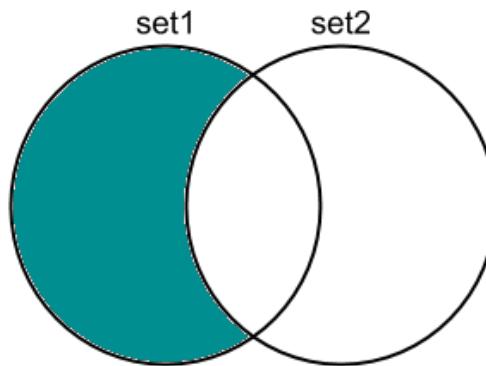

```
for (int i = 0; i < set.size(); i++) {
    do something with set[i];
} // does not compile
```

it is
that doesn't work

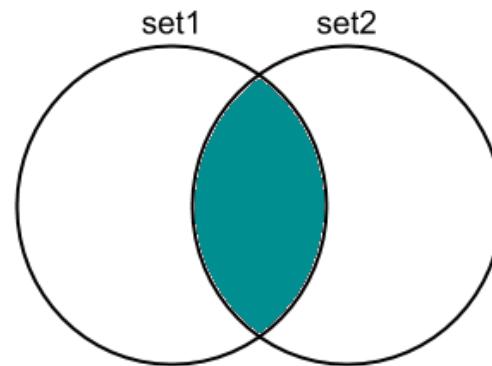

Good Operations to Know

Union: $\text{set1} + \text{set2}$

Difference: $\text{set1} - \text{set2}$

Intersection: $\text{set1} * \text{set2}$

Sets – Method List

<code>s.add(<i>value</i>)</code>	O(log N)	Adds an element to this set, if it was not already there
<code>s.clear()</code>	O(N)	Removes all elements from this set
<code>s.contains(<i>value</i>)</code>	O(log N)	Returns true if <i>value</i> is in this set
<code>s.equals(<i>set</i>)</code>	O(N)	Returns true if the two sets contain the same elements
<code>s.first()</code>	O(log N)	Returns the first value in the set in order
<code>s.isEmpty()</code>	O(1)	Returns true if the set contains no elements
<code>s.isSubsetOf(<i>s2</i>)</code>	O(N)	Returns true if all the elements in the set are also in <i>s2</i>
<code>s.remove(<i>value</i>)</code>	O(log N)	Removes an element from this set
<code>s.size()</code>	O(1)	Returns the number of elements in this set
<code>s.toString()</code>	O(N)	Converts the set to a printable string representation

Set members

```
#include "set.h"
#include "hashset.h"
```

Member	Set	HashSet	Description
<code>s.add(value);</code>	$O(\log N)$	O(1)	adds given value to set
<code>s.clear();</code>	$O(N)$	$O(N)$	removes all elements of set
<code>s.contains(value)</code>	$O(\log N)$	O(1)	true if given value is found
<code>s.isEmpty()</code>	$O(1)$	$O(1)$	true if set contains no elements
<code>s.isSubsetOf(set)</code>	$O(N \log N)$	$O(N)$	true if set contains all of this one
<code>s.remove(value);</code>	$O(\log N)$	O(1)	removes given value from set
<code>s.size()</code>	$O(1)$	$O(1)$	number of elements in set
<code>s.toString()</code>	$O(N)$	$O(N)$	e.g "{3, 42, -7, 15}"
<code>ostr << s</code>	$O(N)$	$O(N)$	print set to stream

Set operators

<code>s1 == s2</code>	true if the sets contain exactly the same elements
<code>s1 != s2</code>	true if the sets don't contain the same elements
<code>s1 + s2</code>	returns the union of s1 and s2 (elements from either)
<code>s1 += s2;</code>	sets s1 to the union of s1 and s2 (or adds a value to s1)
<code>s1 * s2</code>	returns intersection of s1 and s2 (elements in both)
<code>s1 *= s2;</code>	sets s1 to the intersection of s1 and s2
<code>s1 - s2</code>	returns difference of s1, s2 (elements in s1 but not s2)
<code>s1 -= s2;</code>	sets s1 to the difference of s1 and s2 (or removes a value from s1)

```
Set<string> set;
set += "Jess";
set += "Alex";
Set<string> set2 {"a", "b", "c"}; // initializer list
... and differences
... using operators
```

Set exercise

- Write a function **isHappyNumber** that returns whether a given integer is "happy". An integer is "happy" if repeatedly summing the squares of its digits eventually leads to the number 1.

– Examples:

139 is happy:

$$1^2 + 3^2 + 9^2 = 91$$

$$9^2 + 1^2 = 82$$

$$8^2 + 2^2 = 68$$

$$6^2 + 8^2 = 100$$

$$1^2 + 0^2 + 0^2 = \textcolor{blue}{1}$$

4 is unhappy:

$$4^2 = 16$$

$$1^2 + 6^2 = 37$$

$$3^2 + 7^2 = 58$$

$$5^2 + 8^2 = 89$$

$$8^2 + 9^2 = 145$$

$$1^2 + 4^2 + 5^2 = 42$$

$$4^2 + 2^2 = 20$$

$$2^2 + 0^2 = \textcolor{red}{4}$$

that doesn't work there okay

all right um

– How can this problem be solved using a set?

Structs

- C++ has an entity called a *structure (struct)*.
 - Like a lightweight class; a collection of data and behavior.
 - By default, member variables and methods are public.

```
struct Date {           // declaring a struct type
    int month;
    int day;            // members of each Date structure
};

...
Date today;           // construct structure instances
today.month = 7;
today.day = 13;

Date xmas {12, 25};   // initialize on one line
no methods but just two instance
variables
```

Set/HashSet of structs

- By default, our libs can't store your struct in a Set or HashSet.
 - To be in a Set, your struct needs to be sortable using a **< operator**.
 - To be in a HashSet, you need **==**, **!=**, and a **hashCode** function.
 - We will talk about these ideas in much more detail later.

```
// operator overloading; define < operation on dates
// (required in order to put Date in a Set)
bool operator <(const Date& d1, const Date& d2) {
    return d1.month < d2.month
        || (d1.month == d2.month && d1.day < d2.day);
}

// converts a Date into an integer key
// (required in order to put Date in a HashSet)
int hashCode(const Date& date) {
    return date.month * 100 + date.day;
}
```

```
31
32     - ostream& operator<<(ostream& out, const Date& d) {
33         ... out << d.month << "/" << d.day;
34         ... return out;
35     }
36
37     - int main() {
38
39         ... Date xmas {12, 25};
40         ... Date bday {9, 19};
41         ... Set<Date> calendar;
42         ... calendar.add(bday);
43         ... calendar.add(xmas);
44         ... cout << "dates are: " << calendar << endl;
```

some other time but
if you want to make something printable

Today's Topics

- Sets (no duplicates allowed!)
 - Lexicons
- Maps (map a key to a value)

Lexicons

- Set where the only type is string
- Can do everything a Set does
- Also answers the question – do any words start with this prefix?
 - `lexicon.containsPrefix(prefix)`
- Used to store dictionaries
- We'll talk about lexicons more later

Stanford Lexicon (5.6)

```
#include "lexicon.h"
```

- A set of words optimized for dictionary and prefix lookups

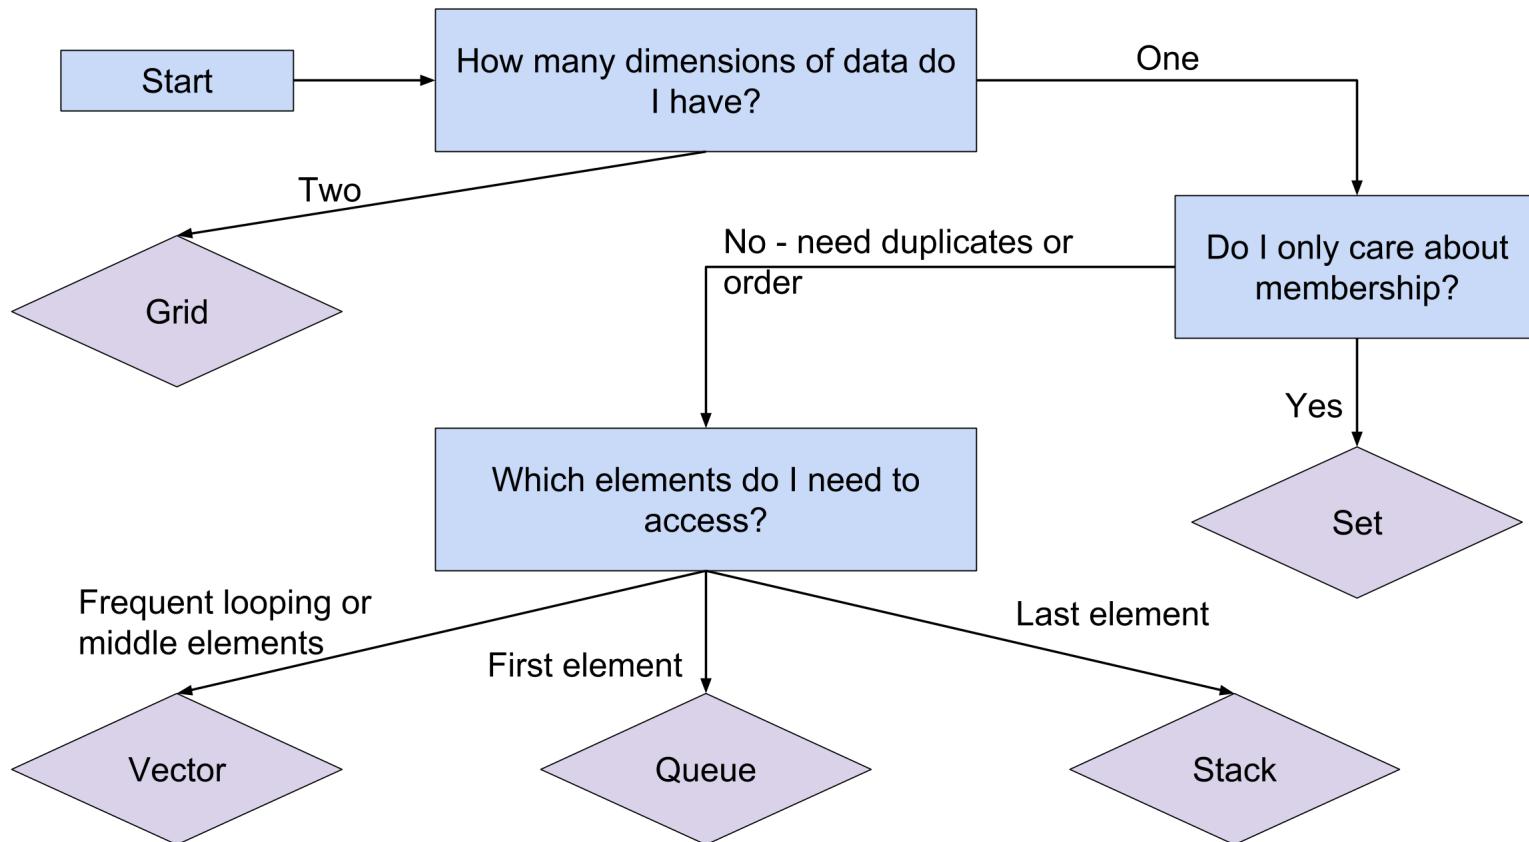

Member	Big-Oh	Description
<code>Lexicon <i>name</i>;</code> <code>Lexicon <i>name</i>("<i>file</i>");</code>	$O(N*len)$	create empty lexicon or read from file
<code><i>L</i>.add(<i>word</i>);</code>	$O(len)$	adds the given word to lexicon
<code><i>L</i>.addWordsFromFile("f");</code>	$O(N*len)$	adds all words from input file (one per line)
<code><i>L</i>.clear();</code>	$O(N*len)$	removes all elements of lexicon
<code><i>L</i>.contains("word")</code>	$O(len)$	true if word is found in lexicon
<code><i>L</i>.containsPrefix("str")</code>	$O(len)$	true if s is the start of any word in lexicon
<code><i>L</i>.isEmpty()</code>	$O(1)$	true if lexicon contains no words
<code><i>L</i>.remove("word");</code>	$O(len)$	removes word from lexicon, if present
<code><i>L</i>.removePrefix("str");</code>	$O(len)$	removes all words that start with prefix
<code><i>L</i>.size()</code>	$O(1)$	number of elements in lexicon
<code><i>L</i>.toString()</code>	$O(N)$	e.g. {"arm", "cot", "zebra"}

Lexicon example

```
#include "lexicon.h"
...
// read file into a dictionary lexicon
Lexicon dictionary;
dictionary.addWordsFromFile("dict.txt");

// look up words/prefixes in the dictionary
string word = getLine("type a word: ");
if (dictionary.contains(word)) {
    cout << "That word is in the dictionary!" << endl;
} else if (dictionary.containsPrefix(word)) {
    cout << "Some words start with " << word << endl;
}
print the words in sorted order
yep uh okay
```

ADTs Expanded

Today's Topics

- Sets (no duplicates allowed!)
 - Lexicons
- Maps (map a key to a value)

Maps

- Stores **pairs** of information
 - First half of the pair is called a **key**, and the second half is the associated **value**
 - Find a value by looking up its associated key
 - Keys must be unique (just like elements in a Set!)
- Comparison with Vector
 - Vectors look up elements by *index*, Maps look them up by *key*
 - Need to declare two types (for the key and the value)
 - Ordered by key, not index

Map Syntax

- *map.put(key, value)*
 - *map[key] = value*
 - Adds the key if it wasn't already in the map
 - Otherwise edits its value
- *map.get(key)*
 - *map[key]*
 - This alternate syntax will create a key with the **default** value in the map
- *map.remove(key)*
 - No effect if the key isn't in the map

Map Example: Dictionary

```
ifstream file;
promptUserForFile(file, "Where is your dictionary?");
Map<string, string> dictionary;
string word;

while (getline(file, word)) {
    string definition;
    getline(file, definition);
    dictionary[word] = definition;
}

while (true) {
    string query = getLine("Word to look up?");
    if (dictionary.containsKey(query)) {
        cout << "The definition is " << dictionary[query] << endl;
    } else {
        cout << "I don't know that word!" << endl;
    }
}
```

Looping over Maps

- Maps also don't have indices, so we use a for-each loop over the keys
- Iterates in sorted order over the keys
- Can't edit the keys while we iterate (can edit values)

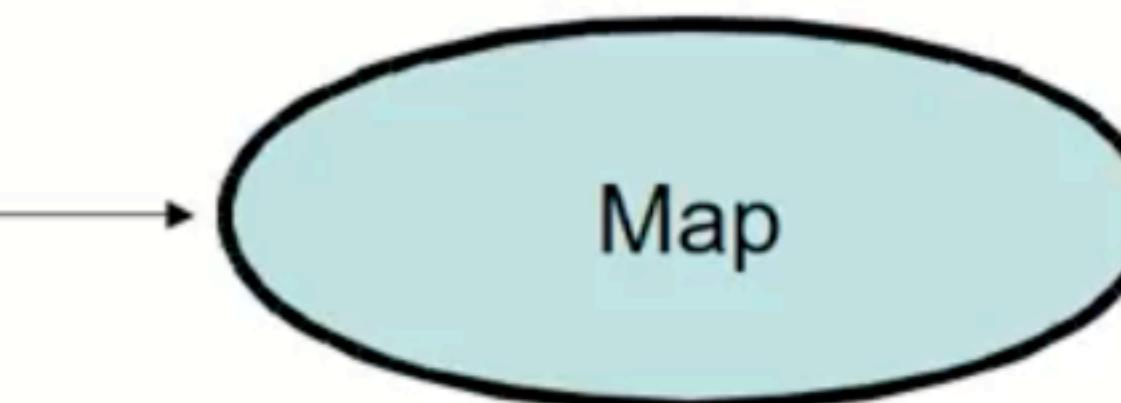

```
Map<string, int> phonebook;
phonebook["Tyler"] = 5551234;
phonebook["Kate"] = 5559876;
```

```
// prints in alphabetical order
for (string name: phonebook) {
    int phoneNumber = phonebook[name];
    cout << "I'm going to call " << name;
    cout << " at " << phoneNumber << endl;
}
```

Using maps

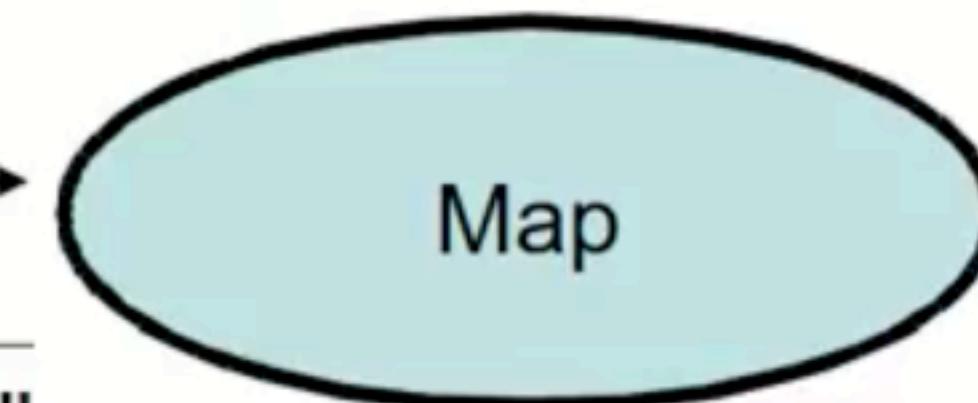

- A map allows you to get from one half of a pair to the other.
 - Remembers one piece of information about every index (key).
Store pair ("Suzy", "206-685-2181").

```
//      key          value
// m["Suzy"] = "206-685-2181";
m.put("Suzy", "206-685-2181");
```

- Later, we can supply only the key and get back the related value:
What is Suzy's phone number?

```
// m["Suzy"]
m.get("Suzy")
```

Map implementation

- in the Stanford C++ library, there are two map classes:
 - **Map**: implemented using a linked structure called a *binary search tree*.
 - pretty fast for all operations; keys are stored in **sorted order**
 - both kinds of maps implement exactly the same operations
 - the keys' type must be a comparable type with a < operation
 - **HashMap**: implemented using a special array called a *hash table*.
 - *very* fast, but keys are stored in unpredictable order
 - the keys' type must have a hashCode function (but most types have one)
- Requires 2 type parameters: one for keys, one for values.

```
// maps from string keys to integer values
Map<string, int> votes;
```

Map members

Member	Map	HashMap	Description
<code>m.clear();</code>	O(N)	O(N)	removes all key/value pairs
<code>m.containsKey(key)</code>	O(log N)	O(1)	true if map has a pair with given key
<code>m[key]</code> or <code>m.get(key)</code>	O(log N)	O(1)	returns value mapped to given key; if not found, adds it with a default value
<code>m.isEmpty()</code>	O(1)	O(1)	true if the map contains no pairs
<code>m.keys()</code>	O(N)	O(N)	a Vector copy of all keys in map
<code>m[key] = value;</code> or <code>m.put(key, value);</code>	O(log N)	O(1)	adds a key/value pair; if key already exists, replaces its value
<code>m.remove(key);</code>	O(log N)	O(1)	removes any pair for given key
<code>m.size()</code>	O(1)	O(1)	returns number of pairs in map
<code>m.toString()</code>	O(N)	O(N)	e.g. "{a:90, d:60, c:70}"
<code>m.values()</code>	O(N)	O(N)	a Vector copy of all values in map
<code>ostr << m</code>	O(N)	O(N)	prints map to stream

Word Count

- We've found the number of unique words in a file. Another statistic is how frequently each word is used.
- Given a text file and a user-inputted word, how frequently is that word used in the file?

```
to be or not to be
```

tiny.txt

File? `tiny.txt`

Word? `to`

"to" appears 2 times

Word? `or`

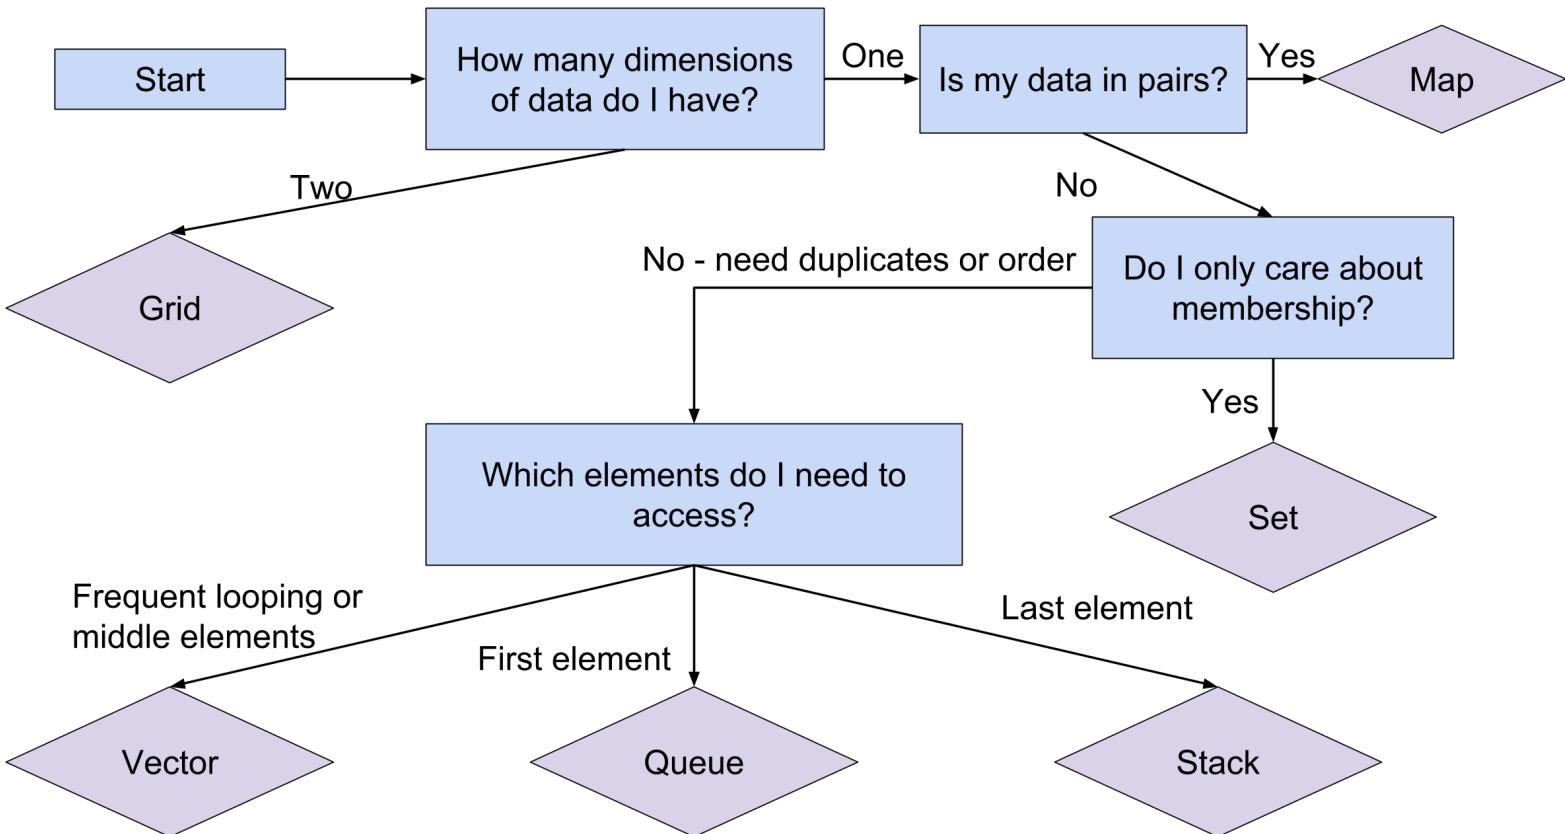

"or" appears 1 times

Solution

```
int main() {
    ifstream infile;
    promptUserForFile(infile, "File?");
    Map<string, int> map;
    string word;
    while (infile >> word) {
        map[word]++;
    }
    infile.close();

    string userWord = getLine("Enter a word (or enter to quit): ");
    while (userWord != "") {
        if (map.containsKey(userWord)) {
            cout << "\"" << userWord << "\"" << " appears " << map[userWord] << " times."
<< endl;
        }
        userWord = getLine("Enter a word (or enter to quit): ");
    }
    return 0;
}
```

ADT Soup

Anagram exercise

- Write a program to find all **anagrams** of a word the user types.

Type a word [Enter to quit]: **scared**

Anagrams of scared:

cadres

cedars

sacred

scared

- What is a good compound collection to use on this problem?

Nesting ADTs: Where2Eat

- Problem: we want to schedule a dinner with some group of our friends
- We have a text file with all our friends' dinner preferences
- Given a group of friends going to a dinner, where should we eat to maximize happiness?
 - We might not be able to find a place that makes everyone happy – such is life
- Which ADT(s) should we use?

Ashley
In n Out
Chipotle
Axe and Palm

Ketan
Chipotle
Bytes Cafe

Karel
Bytes Café
Forbes Cafe

Solution

```
int main() {
    ifstream file;
    file.open("restaurants.txt");
    Map<string, Set<string> > map;

    string myFriend;
    while (getline(file, myFriend)) {
        string restaurant;
        while (getline(file, restaurant) &&
    restaurant != "") {
            map[myFriend] += restaurant;
        }
    }
    Set<string> guests;
    string guest = getLine("Enter a guest: ");
```

```
    while (guest != "") {
        while (guest != "") {
            guests.add(guest);
            guest = getLine("Enter a guest: ");
        }
        cout << "Here are the acceptable
    restaurants:" << endl;
        Set<string> restaurants;
        for (string guest : guests) {
            if (restaurants.isEmpty()) {
                restaurants = map[guest];
            } else {
                restaurants *= map[guest];
            }
        }
        for (string restaurant : restaurants) {
            cout << restaurant << endl;
        }
    }
    return 0;
}
```

Closing Remarks

- Sets/Maps do extend functionality past the vector unlike what we saw with stack/queue. If stack/queue didn't extend functionality, why do we care about them?
- Example counting words in books using a vector and `vec.contains(...)`. Really slow. Now switch vector to set and goes much faster. Why?
- Stack/queue does NOT have for-each loop. That would violate our rule of only being able to see the “next” element.

Look Ahead

- Assignment 1 due **today at 5PM**
- Assignment 2 comes out today, due **Wednesday, July 10 at 5PM**
